# AI-Native Playbook: From Solo to Scalable

**Date & time:** Oct. 14, 11:40 AM-12:15 PM EST
**Track:** Applied AI

## Keith Moehring

CEO, L2 Digital

- LinkedIn

## Session Description

Everyone says AI can help you scale, but what does that actually look like? A year ago, Keith Moehring set out to answer that question by transforming a one-person business with real marketing, sales, service, and product demands into an AI-native company.

In this session, Moehring will share the real-world playbook he used to build an AI-native operation supported by automations, agents, and feedback loops. He'll walk through the process, resources, tools, and technologies used to bring AI into the day-to-day execution and management of the business, and show how a simple org chart helped keep the system cohesive and aligned. He also won't shy away from sharing all the glorious faceplants along the way.

## Key Quote

> *"I built an operating system, and then I gave AI access to that operating system, and my favorite part is that entire operating system sits in a folder on my desktop."* **- Keith Moehring**

## Session Summary

Keith Moehring, founder and CEO of L2 Digital, shared how he turned two businesses into AI-native operations: Playthrough, a live golf scoring platform he built and ran as a side project for 10 years, and L2 Digital, where he builds AI automations for sales and marketing teams. He said about 80% of his ongoing client work now runs through AI and automations, cutting the time per client from 20 to 30 hours a month to five to eight. He credited that not to refining a few processes but to building an operating system and giving AI access to it, and he framed the entire session as a step-by-step "how."

Moehring argued that while AI transformation needs top-down support, the operating system gets built from the subtask level up: automate most of one subtask, then the next, until whole tasks and functions run largely on AI. Drawing on Nate Herk's automation hierarchy, he walked through the spectrum from simple workflows to AI-assisted workflows, AI chat, AI orchestrators and AI agents, noting that each step up trades predictability for capability. He explained orchestrators with a kitchen analogy, where the AI model is the chef, skills are the instructions, context such as guides, templates and data are the ingredients, and connectors are the tools.

For the prep work, he recommended choosing the subtask you most hate doing, performing it manually five times while documenting every step and decision, timing yourself to set an ROI benchmark, and then aggressively simplifying the process before automating it. He then introduced his seven Ps framework, adapted from Katie Robbert and Chris Penn's 5P framework,

which covers the purpose, the “please” (the prompt and its variables), the process steps, the platforms involved, the human checkpoints, the outputs and the performance metrics. He shared a tool that turns those answers into an instruction document AI can use to build the automation.

On building, Moehring described two paths: plugins in ChatGPT, which package skills, reference docs and connectors into a repeatable unit, or a local folder on the desktop paired with a coding tool such as Cursor, Claude Code or Codex, set up with his downloadable “start here” file. He closed with lessons on rollout, urging a crawl, walk, run approach with close review and feedback before granting more autonomy, tight limits on agents with more than read-only access, and an AI-generated HTML operating manual to keep track of a growing library of automations and skills.

## Key Takeaways

- **Build from the subtask up.** Leadership support matters, but the AI operating system comes together by automating individual subtasks until whole tasks and functions run largely on AI.
- **Start with the task you hate.** Do it manually five times, document every step and decision, and time yourself so you have a benchmark to prove ROI later.
- **Simplify before you automate.** Strip a process down to its core steps first, because automations built around bloated processes are hard to change once they are in place.
- **Write a clear instruction doc.** Use the seven Ps to define purpose, prompt, process, platforms, human checkpoints, outputs and performance so AI has what it needs to build the automation.
- **Meet users where they live.** Deliver outputs in the format and place people already work, like a single email for a phone-first sales team instead of a CRM they won’t open.
- **Crawl, walk, run, but never sprint.** Review and coach every output before granting autonomy, and assume that if an AI can do something, it eventually will.
